**ABSTRACT:** Self-incompatibility is a cell-cell recognition system in higher plants that is based on the ability of the pistil to distinguish non-self pollen from self pollen. In *Petunia hybrida*, self-incompatibility is controlled by a single locus, the S-locus. The sequences governing S-RNase expression are not known and an understanding of this would enable us to better manipulate self-incompatibility response in flowers. This study attempted to correlate the degree of reporter gene activity with varying amount of 5' flanking sequence present on different gene constructs. Reporter gene activity was assayed by fluorometric measurements of GUS ( $\beta$ -glucuronidase) enzyme activity normalized to total soluble protein. Pistils were collected from transgenic plants with different gene constructs and protein extracts prepared. Extracts were used for protein and enzyme assays. Of the 34 plants assayed, only 5 showed GUS expression above background. Because of this low number of plants expressing GUS, we were unable to draw any conclusion about the effect of 5' flanking sequences on S-RNase expression.

## Introduction

Various mechanisms in flowering plants have evolved to prevent the tendency of self-fertilization created by close proximity of male and female reproductive organs in a perfect flower. One such mechanism called self-incompatibility (SI), allows the pistil of a plant to reject self pollen or pollen from genetically related individuals, thus preventing inbreeding and promoting outcrosses. With this mechanism, in case of a self-pollination of a self-incompatible plant, pollen either fails to germinate or, if it does germinate, the pollen tubes develop abnormally. Self-fertilization is thereby averted. Genetic studies carried on earlier led to the identification of two different types of SI: gametophytic self-incompatibility (GSI) and sporophytic self-incompatibility (SSI). For GSI, the behavior of the pollen is determined by the genotype of the pollen grain itself, whereas for SSI, the SI behavior of the pollen is determined by the genotype of the parent plant. This difference most likely reflects the difference in the site of expression of the pollen S-allele (see Review Sims, 1993).

In GSI, S-allele proteins are non-specific ribonucleases referred to as S-RNases. These proteins are required for self-incompatibility in styles. It has been seen that lowering the level of S-RNase mRNA has direct correlation to the loss of self-incompatibility in styles. The S-locus mRNA accumulates to high levels during the development of a flower, with the most pronounced increase occurring when the plant becomes self-incompatible from being self-compatible. Studies have shown that S-RNase protein is secreted into the inter-cellular spaces of the transmitting tract, where it accumulates to high levels (Sims, 1993).

In order to analyze the sequences regulating the specific developmental expression of S-locus, Clark *et al* (1994) used microprojectile bombardment to introduce S-allele/ $\beta$ -

glucuronidase (GUS) fusion genes into detached styles or intact pistils for transient expression assays. Various deletion clones having different amounts of S<sub>1</sub> 5' flanking sequence were fused to the GUS reporter gene. They noted that plants with the different constructs all showed positive histochemical staining in styles and petals. Constructs having only 19bp of 5' flanking DNA, and lacking a TATA box as well as promoter-less GUS plasmids did not show positive histochemical staining.

The purpose of this paper was to find out (1) whether the S<sub>1</sub>-GUS constructs were expressed in transgenic *Petunia hybrida*, (2) whether they were expressed in the same qualitative fashion as endogenous S-RNase and (3) whether there was variation in quantitative expression related to the gene construct ( i.e. amount of 5' flanking sequence used).

## **Materials and Methods**

### **Preparation for Assays:**

Styles were collected from flowers of plants transformed with different constructs. Extracts were made by grinding the styles in liquid nitrogen and then adding the frozen powder to 2 ml of GUS extraction buffer (1M Na<sub>2</sub>HPO<sub>4</sub>, 1M NaH<sub>2</sub>PO<sub>4</sub>, 0.5M Na<sub>2</sub>EDTA pH 8, 10% Triton X-100, 0.1% Na-N-lauroyl-sarcosine). The cell debris was pelleted in a microcentrifuge at maximum speed for ten minutes, the supernatant taken out and either used for the assays directly or frozen for use in future assays.

### **Protein Assay :**

First a protein standard assay was done so that a standard curve could be determined. For that seven test tubes were set up with 0.1ml of diluted protein standard (Bio-Rad) with actually had 0µg, 13µg, 26µg, 52µg, 77µg, 103µg and 129µg of the protein standard. 5ml of diluted dye

reagent was added to these tubes and they were let to stand for 15-30 minutes. After this, absorbance was read at  $A_{595}$  using a spectrophotometer and a standard curve drawn with the protein concentration on the x-axis and the absorbance along the y-axis.

For the actual protein assays, 100 $\mu$ l of extract was added to 5ml of diluted dye. If the absorbance reading was off scale, further dilutions were sometimes made with 50 $\mu$ l of the extract and 50 $\mu$ l of extraction buffer instead of the 100 $\mu$ l of the extract. The absorbance was then read and this value was used to find out the corresponding protein concentration from the standard curve.

#### **Fluorometric Assays of GUS Activity:**

250 $\mu$ l of extract was added to 250 $\mu$ l of pre-warmed assay buffer (2mM methylumbelliferyl- $\beta$ -D-glucuronide, MUG, in extraction buffer). 100 $\mu$ l of this solution was then added to 1.9ml of stop buffer (0.2M NaCO<sub>3</sub>). The remaining assay solution was placed in a 37°C waterbath. 100 $\mu$ l aliquots were taken out at 30, 60 and 120 minutes after the initial extraction. Fluorescence was measured using a Hoeffler TKO fluorimeter with 500 fluorescent units (FU) equal to 50nM 4-methylumbelliferone (MU).

#### **Calculations :**

A graph was plotted with absorbance on the y-axis and time on the x-axis. The gradient of this graph was later used for the calculation of specific enzyme activity.

1. The corresponding concentration of protein ( [prot] ) was read off of a standard curve showing absorbance against [prot] in mg/ml.
2. This was then converted into prot in mg/ml.
3. The readings from the fluorometric analysis were plotted for each plant and the slope of this line gave us the fluorescence unit (FU)/min.

4. To calculate Specific Enzyme Activity (SA):

- a) Conversion of FU/min to nM/min.

For standard (50nM), FU = 500

In 2.0ml, 50 nM =  $1 \times 10^{-10}$  moles MU.

- b)  $[(FU \text{ min}^{-1}) \times (2\text{ml}/0.1\text{ml}^*) \times (0.5\text{ml}/\text{extract vol})]$

$$\text{TFU} = \text{FU} \times 20 \times 2 = (40 \times \text{FU}) \text{FU min}^{-1}\text{ml}^{-1}$$

$$\text{or } \text{FU} \times 40 \times 10 = (400 \times \text{FU})$$

note: extract volume is either 0.25ml or 0.1ml depending on the dilutions.

\* or 0.05ml depending on dilutions.

- c)  $\frac{\text{TFU min}^{-1}}{500} \times 1 \times 10^{-10} \text{ moles} = \frac{\text{moles MU}}{\text{min}}$

$$= \frac{(40)(\text{FU})}{500} \text{ or } \frac{(400)(\text{FU})}{500} = [(0.08 \times \text{FU}) \text{ or } (0.8 \times \text{FU})(1 \times 10^{-10})]$$

- d)  $\text{SA} = \frac{\text{moles MU min}^{-1} \text{ ml}^{-1}}{[\text{prot}]} = \text{moles MU min}^{-1}\text{mg}^{-1}$

$$= \{(0.08 \times \text{FU})/[\text{prot}] \text{ or } (0.8 \times \text{FU})/[\text{prot}]\}(1 \times 10^{-10})$$

- e) conversion of moles MU min<sup>-1</sup>mg<sup>-1</sup> to nmoles MU

$$\text{min}^{-1}\text{mg}^{-1} = \text{SA} / 1 \times 10^{-9}$$

$$\text{or } \text{SA} = \{(0.08 \times \text{FU}) \times 0.1\}/[\text{prot}] \text{ or } \{(0.8 \times \text{FU}) \times 0.1\}/[\text{prot}].$$

Example of Calculation:

For plant # 1-3,

$$\text{prot abs} = 0.54 = 30.93 \mu\text{g/ml prot} = 0.309 \text{ mg/ml prot}$$

$$[\text{prot}] = 0.309$$

$$\text{FU} = 29.68$$

Therefore, SA=[(0.008 X 29.68)/0.309]=0.768 nmole MU min<sup>-1</sup>mg<sup>-1</sup>

## **Results**

### **Deletion Constructs and Plant Transformation**

In an attempt to specifically identify cis-acting regulatory sequences, a series of exonuclease-III deletion clones (Clark and Sims, 1994) containing variable amounts of 5'-flanking sequence, were subcloned into the transformation vector pGSC1700 (Cornellisen and Vandewiele, 1989). The deletion clones used in this study have the following amounts of 5'-flanking sequence: #1--- none (GUS cassette only), #2--- 8kb, #4 --- 1.9kb, #5 ---425 bp. These constructs were used for transformation of leaf disks of a *Petunia hybrida* S<sub>1</sub>S<sub>1</sub> line, and plants regenerated (Ashraf and Sims, unpublished). Transformed plants were selected by regeneration on media containing kanamycin.

### **Fluorometric Assays of β-glucuronidase (GUS) Activity in Transgenic Plants**

Thirty four individual plants were assayed for GUS activity (see Methods). Of these, 1 was #1 (pUC-GUS), 7 were #2 (S<sub>1</sub>-8kb-GUS), 14 were #4 (S<sub>1</sub>-2kb-GUS) and 12 were #5 (S<sub>1</sub>-450-GUS). Also, there were 4 non-transformed S<sub>1</sub>S<sub>1</sub> which were used as controls. Out of all the plants assayed , only 5 plants showed expression greater than the background (Table 1). The result of the assays is given in Table 2.

**Calculations after data collection:**

Plants showing greater expression than background:

**Table 1**

#	Plant #	Average SA(nM/min/mg)	Difference (AvgSA-x)
1	2-32	1.271	0.039
2	4-27	5.69	4.458
3	4-9	3.14	1.911
4	4-13	4.51	3.273
5	4-20	1.33	0.098

**Figure 2**

Mean of background (controls),  $x = 1.232$

## Discussion

Out of all the plants (34) that were used for the fluorometric assays only five (14.7%) of them showed GUS expression greater than the background. Of these plants, one was plant 2-32 with the construct S<sub>1</sub>-8kb-GUS and the other four were plants 4-27, 4-9, 4-13 and 4-20 with the constructs S<sub>1</sub>-2kb-GUS.

No conclusions can be drawn on the effect of 5' flanking sequence amount on gene expression based on these results. The reasons why so few plants showed GUS expression could be either of the following: (1) The plants were not transformed in the first place. This is unlikely since these plants were Kan<sup>R</sup> when tested, and therefore should have the transformed construct.

(2) Alternatively, only a few transgenic plants showed high levels of GUS expression, probably due to "position effects". Earlier experiments (see Sims *et al* 1993), had also given mixed results. For example, Murfett *et al* (1995), had tested the effects of S<sub>2</sub>, S<sub>6</sub> and S<sub>A2</sub> promoters from *Nicotiana alata* in several hosts. Expression was only observed with the S<sub>6</sub> promoter in *N. alata*, and in that case the level of expression was estimated to be 300-fold below that of endogenous S<sub>6</sub> expression. Also, in work done by Lee *et al* (1994), only about 3% of the total transformants assayed gave levels of expression comparable to endogenous S-RNase expression.

The number of plants that I had screened was probably not sufficient to draw any definite conclusion. Work with transgenic plants have shown that a large number of plants have to be screened before any lines expressing transgenes can be obtained.
